## Abstract

This case presents a 46-year-old female patient with advanced pulmonary hypertension referred to our center due to typical symptoms of acute coronary syndrome. Coronary computed tomography angiography revealed severe stenosis of the left main coronary artery caused by compression of the artery by the dilated main pulmonary artery. A good quality computed tomography study enabled precise planning of surgery and was more useful than invasive coronary angiography.

**Key words:** coronary computed tomography, left main compression, acute coronary syndrome

## Streszczenie

Przedstawiamy przypadek 46-letniej pacjentki z zaawansowanym nadciśnieniem płucnym skierowanej do naszego ośrodka z typowymi objawami ostrego zespołu wieńcowego. Dzięki wykonaniu badania metodą tomografii komputerowej tętnic wieńcowych możliwe było rozpoznanie ciasnego zwężenia pnia lewej tętnicy wieńcowej spowodowanego jego kompresją przez poszerzony pień płucny. Badanie tomografii komputerowej dobrej jakości umożliwiło precyzyjne zaplanowanie zabiegu i okazało się bardziej przydatne niż koronarografia inwazyjna.

**Słowa kluczowe:** tomografia komputerowa, kompresja pnia lewej tętnicy wieńcowej, ostry zespół wieńcowy

## Case report

A 46-year-old female patient with severe idiopathic pulmonary hypertension treated with sildenafil and a prostacyclin analogue in NYHA class III/IV was transferred to the Institute of Cardiology because of anginal pains. Crescendo angina had begun a few weeks before the hospitalization and in the recent period had taken the form of recurrent resting pains. Electrocardiogram showed right bundle branch block with oscillating myocardial ischaemia during angina.

Echocardiographic examination confirmed the presence of pulmonary hypertension with aneurysmal dilation of the pulmonary trunk (maximal diameter of 44 mm) and a dilated, hypokinetic right ventricle. Left ventricular contractility and volume were assessed as normal. Laboratory examinations demonstrated an increased troponin level. Because of the patient's clinical instability an emergency computed tomography (CT) of the coronary arteries was performed.

### Diagnostic imaging and treatment planning

The study was performed using a 128 slice dual source scanner (Somatom Definition Flash – Siemens, Germany) and an acquisition protocol optimized for the assessment of coronary arteries. Because of the fast resting heart rate (82 bpm) a protocol with retrospective ECG gating was used. Scan time was 4.8 s and 60 ml of a high-iodine concentration contrast agent (Iomeron 400 – Bracco, Italy) was administered. Total radiation dose of the study was 6.2 mSv.

Computed tomography excluded the presence of coronary anomalies and atherosclerotic plaques in coronary arteries, but showed a critical stenosis of the ostium of the left main coronary artery (LMCA) caused by compression from the aneurysmally dilated pulmonary trunk (Figure 1 A-F). Minimal lumen area of the left main coronary artery was less than  $3.0 \text{ mm}^2$ .

Because of the unstable clinical condition, after detailed assessment of the anatomical relations shown in com-

puted tomography, the patient was offered treatment by means of a percutaneous coronary intervention.

Computed tomography allowed a precise assessment of the anatomical conditions and therefore permitted planning of the percutaneous coronary intervention. MPR, cMPR and VRT reconstruction images were used to assess the length of the LMCA, the length of stenosis and the reference diameter of the vessel (Figure 2 A-D). Precise assessment of the lesion length was also possible by means of transverse views similar to those obtained with intravascular ultrasound (Figure 2 A-D). Image analysis permitted planning of the procedure consisting of stent implantation to the proximal LMCA segment without the need of bifurcation involvement.

After signing informed written consent the patient received dual antiplatelet therapy and was prepared for the procedure.

### Percutaneous coronary intervention

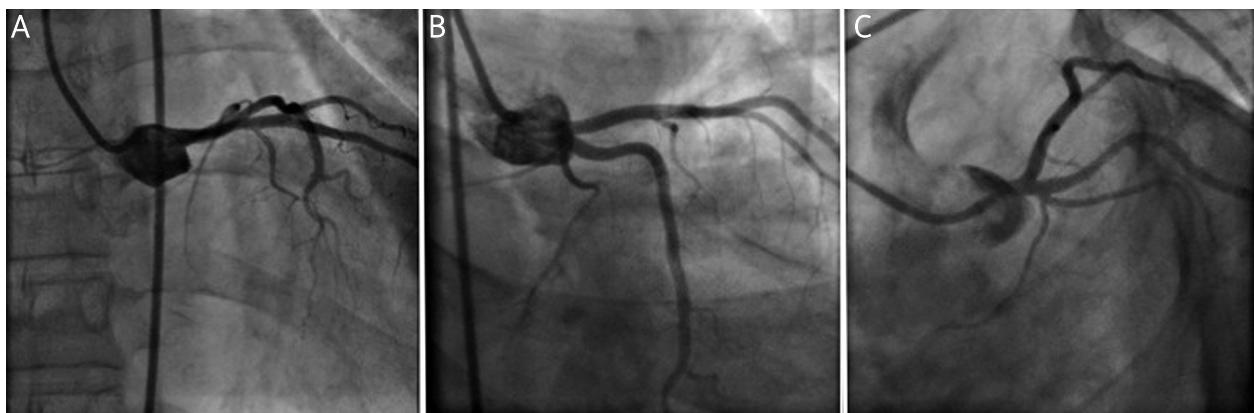

Left main coronary artery stenosis was not seen in the few initial, typical left coronary artery views (Figure 3 A-C). Additional, atypical views planned according to the CT scan were necessary to demonstrate the compression of the left main ostium (Figure 4 A-B). It was impossible to find a view showing the ostium and the bifurcation of the left main coronary artery at the same time. Therefore precise planning of the stent length based solely on coronary angiography might have been inaccurate. Finally, based on the CT measurements, a stent of 4.0 mm diameter and 12 mm length was chosen (Figure 4 C). Optimal stent length was confirmed in two views (Figures 4 C, 5 A). The stent was post-dilated with a short (10 mm) high-pressure (non-compliant) balloon to reach the reference diameter of the vessel assessed by CT (Figure 5 B). A very

**Fig. 2.** Computed tomography of the coronary arteries, MIP presentation: A-B – views allowing precise planning of the stent length; C – serial images in transverse views similar to the images from intravascular ultrasound; D – transverse projection – measurement of reference diameter of the vessel – planning of the stent diameter

**Fig. 3.** Angiography of the left coronary artery: A-C – three typical views do not show the significant ostial LMCA stenosis

**Ryc. 3.** Koronarografia lewej tętnicy wieńcowej: A-C – trzy typowe projekcje niepokazujące istotnego zwężenia w ujściu pnia LTW

**Fig. 4.** Angiography of the left coronary artery: A-B – additional views elucidate a tight stenosis described before in computed tomography; C – positioning of the stent whose diameter and length were adjusted according to the computed tomography; one of the guidewires is placed in the left anterior descending artery and the second one in the left coronary sinus

**Ryc. 4.** Koronarografia lewej tętnicy wieńcowej: A-B – dodatkowe projekcje ujawniają ciasne zwężenie, opisane wcześniej w badaniu metodą tomografii komputerowej; C – pozycjonowanie stentu o średnicy i długości dobranej na podstawie badania metodą tomografii komputerowej, jeden z prowadników wprowadzony do gałęzi przedniej zstępującej, drugi znajduje się w lewej zatoce wieńcowej

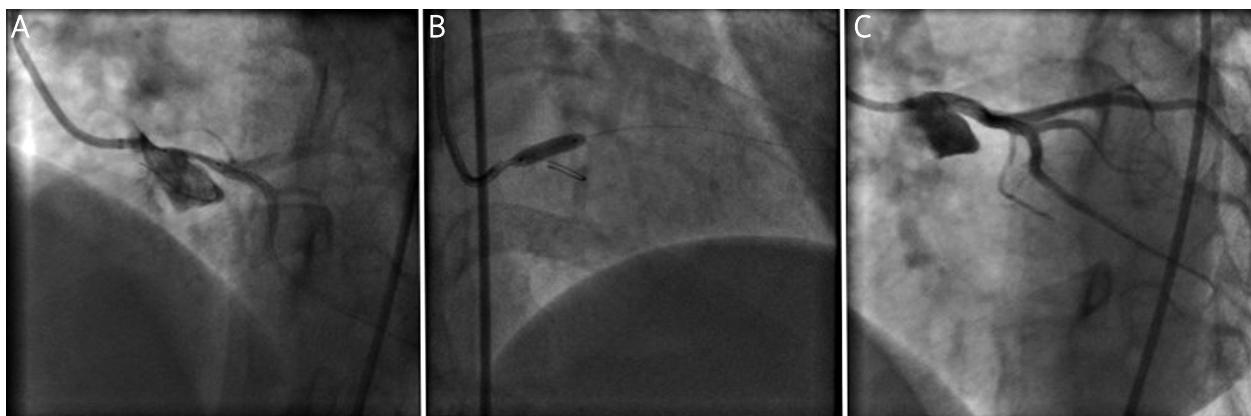

good angiographic effect of the procedure was obtained (Figure 5 C).

No complications of the procedure were observed. There were no anginal pains in the days following the procedure. Slow normalization of the myocardial necrotic markers was noted.

## Discussion

The described case emphasizes the key role of non-invasive imaging by means of computed tomography in reaching a diagnosis and treatment planning in a patient with atypical pathology. It is probably the first in Poland

and one of the few described cases where CT allowed a fast, safe and accurate diagnosis of an external compression of the left main coronary artery by a markedly dilated pulmonary trunk [1-3]. An indisputable advantage of CT is its possibility to assess anatomical structures beyond assessment of the coronary artery lumen. Data obtained during the CT scan are used for construction of two- or three-dimensional reconstructions which in the present case permitted us to form a definitive diagnosis and to plan an optimal method of treatment. In contrast to classic coronary angiography, CT scan does not have limitations which could in some cases exclude the possibility

**Fig. 5.** Angiography of the left coronary artery: **A** – confirmation of the correct stent length; **B** – stent expansion under 20 atm; **C** – final effect of the procedure

**Ryc. 5.** Koronarografia lewej tętnicy wieńcowej: **A** – potwierdzenie właściwej długości stentu; **B** – rozprężenie stentu ciśnieniem 20 atm; **C** – finalny efekt zabiegu

of a reliable assessment of the vessel length and its reference diameter.

The knowledge about the angiographic picture of the patient before her arrival in the catheterization laboratory permitted us to:

- 1) choose the optimal treatment method (in the present case cardiac surgery was denied due to high risk),
- 2) collect the informed consent in a comfortable way for the patient,
- 3) initiate pre-procedural pharmacotherapy, and
- 4) prepare for the percutaneous procedure (choose a guiding catheter or the right stent in terms of its diameter, length and maximal radial force).

Information based on the good quality images from computed tomography are useful in planning of the interventional and surgical revascularization, not only in the present case, but also in patients with atherosclerotic changes [4, 5]. Computed tomography data have similar quality to coronary angiography supplemented by intravascular ultrasound. In the present case, information about the results of the CT scan was known to the treating physician and to the interventional cardiologist and therefore permitted correct treatment planning and safe conduction of the procedure.
