Summary
Background. Globally, the level of antibiotic prescription in dental care is increasing each year, and evidence shows a high level of antibiotic misuse.

Objectives. The survey was conducted to determine the antibiotic prescription pattern in primary dental care in Kosovo, to analyze prescription habits, to identify eventual misuses of antibiotics and to facilitate the formulation of standards for the rational prescription of these drugs.

Material and methods. The data of 1,825 registered patients for a 1-year period was randomly collected and analyzed concerning antibiotic use and presented by Defined Daily Doses (DDD)/1,000 inhabitants/day as per the standards of WHO methodology.

Results. The prescription rate of antibiotics in the general number of registered patients was 7.9%. The total consumption of antibiotic drugs in dental primary care was 2.17 DDD/1,000 inhabitants/day. The total number of individual antibiotics during the survey was 6 agents. The most used antibiotic was Co-amoxiclav (J01CR02) with 1.16 DID, followed by Amoxicillin (J01CA04) 0.78 DID. While other individual antibiotics were used significantly less, with Ceftriaxone (J01DD04), with a 0.11 DID, Cefalexin (J01DB01), with a 0.09 DID, Procaine Benzyl Penicillin (J01CE09), with a 0.02 DID, and Gentamicin (J01GB03), with a 0.01 DID.

Conclusions. The results of survey indicate a high and irrational prescription of antibiotics in primary dental care in Kosovo. The prescription of broad-spectrum antibiotics may have a negative impact in destroying commensal flora and triggering bacterial resistance. The use of broad-spectrum antibiotic, especially parenteral antibiotics, should be replaced with more narrow-spectrum oral antibiotics, and a more restrictive prescription pattern should be put in place. For the qualitative improvement of prescription of these drug groups, we recommend the implementation of a restrictive antibiotic policy.

Keywords: dentistry, primary healthcare, antibiotic use.

Background
Antibiotics represent one of the most important drug groups in clinical practice, considering their role in the control of infectious diseases and their impact on public health. Dental care service includes different types of care, such as the treatment of odontogenic infections. Globally, the level of antibiotic prescription in dental care is increasing annually, and antibiotics are used extensively in the field of endodontics [1, 2]. These prescription habits reflect the trends of overuse and misuse of antibiotics in dental practice. The extensive utilization of antibiotics in clinical practice has been determined to be a leading factor in the emergence of antibiotic resistance [3]. However, the relationship between the antibiotic prescription rate and bacterial resistance is relatively complex. Evidence indicates that antibiotic use influences resistance, but a persuasive, quantitative relationship between the volume of antibiotic use and bacterial resistance has not yet been established [4]. Antibiotic prescription by dental practitioners has an important impact on the rate of general antibiotic prescription use, and an attempt has been made to establish a surveillance system for the monitoring and control of the use of these drugs [5, 6].

The rational and effective prescription of antimicrobials is imperative in dental practice, and it is necessary to implement an antimicrobial prescription monitoring system and antibiotic stewardship program. One important strategy for reaching the objective of rational antibiotic prescription is the implementation of drug utilization studies, as defined by the World Health Organization (WHO) [7]. Antibiotic utilization studies enable analyses of antibiotic use, provide feedback data on the distribution of prescriptions and measure the effects of restrictive measures on the level of antibiotic use [8, 9]. Hence, such studies are considered a fundamental starting point in establishing an effective antibiotic stewardship program, with the main objectives of improving treatment efficacy and decreasing bacterial resistance; this program can also be used as a pharmaco-epidemiological measure for implementation of a national restrictive antibiotic policy [10]. Systematic reviews of antibiotic use have revealed effective measures by integrating the results of studies demonstrating effective restrictive programs and decreased antibiotic use [11, 12]. Despite systematic monitoring and the extensive antibiotic use programs in developed countries, the data on antibiotic use in most low- and middle-income countries is scarce and insufficient. Specifically, information on antibiotic use in dental practice is widely unavailable. Thus, the use of...
an antimicrobial prescription monitoring system and antibiotic stewardship program will enable the reduction of prescription errors, increase the safety of drugs and reduce the triggering of drug resistance.

Objectives

The survey was conducted to determine the antibiotic prescription pattern in primary dental care in Kosovo, to analyze prescription habits, to identify eventual misuses of antibiotics and to facilitate the formulation of standards for the rational prescription of these drugs.

Material and methods

Ethics Statement

This study was conducted in the six administrative regions of primary dental health care in Kosovo. In each region, the dental services of the Main Family Medicine Center (MFMC) and of one other Family Medicine Center (FMC) were included in the survey. In total, the study was conducted in twelve primary dental care centers in Kosovo.

In this retrospective study, from 27,375 patient records found at the register of primary health care centers involved in the study, 1 of every 15 records was chosen for analysis, for a total of 1,825 patient records. We used the dental patient register from the beginning of January to the end of December 2015. Data was collected manually by our team using an approved protocol for data collection. The members of the collection team attended training on drug utilization.

Methodology

In this study, the data was analyzed using Microsoft® Excel software 2007, USA. The results are presented using descriptive statistics, such as the frequency of distribution. Quantitative analysis was performed using a methodology based on DDD/1,000 inhabitants/day and ATC, according to the WHO [14].

Results

A total of 1,825 patients were included in our survey. Among them, 49.3% were male, and 50.7% were female. The gender distributions did not significantly differ across the 6 regions (regions 01 to 06).

The prescription rate of antibiotics for the total number of registered patients was 7.9%. The percentages of patients treated with antibiotics varied across the regions, ranging from a low of 4.75% in region 01 to a high of 12.8% in region 02; in addition, the rates were 10.5% and 9.2% in regions 04 and 03, respectively. Of the 1,825 patients, 87 (4.8%) underwent surgical interventions, whereas the other 1,738 received pharmacological dental treatment (Table 1).

For the 144 patients who were prescribed antibiotics, 152 antibiotic prescriptions were registered. Comprehensive analyses of antibiotic use revealed that 136 patients were prescribed only 1 antibiotic, whereas 8 received a combination of 2 antibiotics. Of the 8 patients who received 2 antibiotics, 7 received the combination ceftriaxone and gentamicin, and 1 was prescribed the combination of procaine benzylpenicillin and gentamicin.

The antibiotic prescription rate was slightly higher for male patients than for female patients (52% vs. 48%, respectively). In addition, greater differences in this rate between genders were detected among the different regions. Specifically, in regions 01 and 02, more males than females used antibiotics (64.7% and 58.1%, respectively), whereas in regions 03 and 04, more females than males used them (56.7% and 53.1%, respectively).

Analysis of the prescription of antibiotics by generic name and brand name revealed that generic antibiotics were prescribed significantly more frequently than brand name antibiotics (74.3% vs. 25.7%, respectively). Specifically, in regions 02 and 03, generic antibiotics were prescribed at significantly higher rates of 97.7% and 96.7%, respectively, compared with brand name antibiotics, whereas the opposite was observed in region 04, where the prescription rate of brand name antibiotics was 62.5%.

The total percentage of oral antibiotics was significantly higher than that of parenteral antibiotics (78.3% vs. 21.7%, respectively). Absolute prescription rates (100%) for oral antibiotics were registered in regions 01, 05 and 06, whereas in region 02, the rate for parenteral antibiotics was higher than that for oral antibiotics (51.2% vs. 48.8%, respectively) (Table 2).

Analyses of medical records did not indicate that antibiotic sensitivity testing was conducted for any patient. Therefore, we considered that the prescription of antibiotics was performed empirically.

Figure 1 depicts the percentage of utilization for each antibiotic group, presented as DDD/1,000 inhabitants/day (DID). The distribution shows that beta-lactam antibiotics (J01C) were the most frequently used, with a 1.95 DID, whereas other beta-lactams (J01D) and aminoglycosides (J01G) were used significantly less frequently (with 0.2 and 0.01 DDDs, respectively).

Figure 2 shows the DID values for the 6 antibiotics assessed in this survey. The results showed that dentists in primary dental health care in Kosovo prescribed only 6 individual antibiotics. The most frequently used antibiotic was Co-amoxiclav (J01CR02), with a 1.16 DID, followed by Amoxicillin (J01CA04), with a 0.78 DID. Other antibiotics that were used significantly less frequently included Ceftriaxone (J01DD04), with a 0.11 DID, Cefalexin (J01DB01), with a 0.09 DID, Procaine Benzyl Penicillin (J01CE09), with a 0.02 DID, and Gentamicin (J01GB03), with a 0.01 DID.

Overall, 10 classes of diagnosis were recorded for all patients registered in our survey database. The class of diagnosis K08 (other diseases of teeth and supportive structures) was the most common at 41.2%, followed by class K04 (other diseases of hard tissue of teeth) at 37.6% and K02 (dental caries) at 10.8%. Other classes of diagnosis, such as K05 (gingivitis and periodontal diseases), K00 (disorders of tooth development and eruption) and K10 (other jaw diseases), were documented less frequently (Figure 3).

During our survey, 6 classes of diagnosis were recorded for which antibiotics were prescribed (Figure 4). The predominant class was K08 (other diseases of teeth and supportive structures) at 62.5%, followed by class K04 (diseases of hard tissue of teeth) at 37.6% and K02 (dental caries) at 10.8%. Other classes of diagnosis, such as K05 (gingivitis and periodontal diseases), K00 (disorders of tooth development and eruption) and K10 (other jaw diseases), were documented less frequently (Figure 3).

Analyses of medical records did not indicate that antibiotic sensitivity testing was conducted for any patient. Therefore, we considered that the prescription of antibiotics was performed empirically.
spectrum penicillins. The total use of this antibiotic group is significantly higher compared with the results of antibiotic prescription in Croatia (89.4% vs. 69.9%) [18, 19].

Analysis of the different groups of antibiotics revealed that only 3 groups were prescribed, which indicates that the choice of antibiotics by dentists is relatively rational, homogenous and consensual. Furthermore, the evidence obtained from analysis of the prescription rates of the antibiotic groups does not support the prescription of other beta-lactam antibiotics, especially aminoglycosides, without prior antibiotic sensitivity testing [20].

A total of 6 individual antibiotics were recorded in the survey, which is a relatively small number and is attributed to the lack of protocols for the treatment of dental infections in primary dental care. Pipalova et al. presented that in the Czech Republic, there is a decline of narrow-spectrum penicillins by 4.8%, tetracyclines by 3.5% and macrolides by 3.6%, accompanied by an increasing rate of prescription of co-amoxiclav by 8.9% and lincosamides by 8.5% [2].

Interestingly, in our survey, we found no prescription of lincosamides, while there is clinical evidence from general dental practices in Eastern England which support the use of clindamycin in dentistry [21]. From our contact with dental doctors, we revealed that the problematic safety profile of clindamycin with its impact on the destruction of the intestinal bacterial flora of patients is a reason for not prescribing this antibiotic by dentistry doctors. The dentistry doctors did not mention other reasons. Moreover, lincosamides are not in the essential drug list of Ministry of Health for the primary health care level.

The results of the surveys showed that co-amoxiclav, a broad-spectrum antibiotic, was the most frequently prescribed

---

**Discussion**

The surveillance of antibiotic use in primary dental care in Kosovo was a complex and time-consuming process, because the data was manually collected from patient records. As some medical records were not well documented, it was necessary to obtain additional clarification by directly contacting the dentists.

This is the first comprehensive antibiotic surveillance study conducted to assess primary dental care in Kosovo using the WHO methodology for antibiotic use, which is a drug utilization research methodology based on the Anatomic Therapeutic Classification/Defined Daily Dose (ATC/DDD) index [15].

The rate of antibiotic use for the total number of dental patients was 7.9%, which can be considered optimal under the circumstances of this study, because applicable antibiotic treatment guidelines and protocols are not available in Kosovo; thus, there are no restrictions on antibiotic prescription in primary dental care [16]. According to published data, there is an increased trend of antibiotic prescription in primary dental care [16]. According to published data, there is an increased trend of antibiotic prescription in primary dental care [16]. According to published data, there is an increased trend of antibiotic prescription in primary dental care [16].

The total outpatient antibiotic (ATC group J01) use was 2.16
dID and is substantially higher than the prescription of antibiotic by dentist in the Czech Republic (0.75
dID) [2] and in Canada (1.59
dID) [17]. In addition, beta-lactam antibiotics (J01C) were the most frequently used. These antibiotics can be considered a rational choice for use in dental practice, especially narrow-spectrum penicillins. The total use of this antibiotic group is significantly higher compared with the results of antibiotic prescription in Croatia (89.4% vs. 69.9%) [18, 19].

Analysis of the different groups of antibiotics revealed that only 3 groups were prescribed, which indicates that the choice of antibiotics by dentists is relatively rational, homogenous and consensual. Furthermore, the evidence obtained from analysis of the prescription rates of the antibiotic groups does not support the prescription of other beta-lactam antibiotics, especially aminoglycosides, without prior antibiotic sensitivity testing [20].

A total of 6 individual antibiotics were recorded in the survey, which is a relatively small number and is attributed to the lack of protocols for the treatment of dental infections in primary dental care. Pipalova et al. presented that in the Czech Republic, there is a decline of narrow-spectrum penicillins by 4.8%, tetracyclines by 3.5% and macrolides by 3.6%, accompanied by an increasing rate of prescription of co-amoxiclav by 8.9% and lincosamides by 8.5% [2].

Interestingly, in our survey, we found no prescription of lincosamides, while there is clinical evidence from general dental practices in Eastern England which support the use of clindamycin in dentistry [21]. From our contact with dental doctors, we revealed that the problematic safety profile of clindamycin with its impact on the destruction of the intestinal bacterial flora of patients is a reason for not prescribing this antibiotic by dentistry doctors. The dentistry doctors did not mention other reasons. Moreover, lincosamides are not in the essential drug list of Ministry of Health for the primary health care level.

The results of the surveys showed that co-amoxiclav, a broad-spectrum antibiotic, was the most frequently prescribed
drug (with a 1.16 DID) in all regions of Kosovo, and it appears to be the first-line antibiotic for use in the treatment of dental infections. This antibiotic was selected empirically, as the bacterial resistance rate for dental infections in Kosovo was unknown. The rate of prescription of co-amoxiclav was high in contrast with its prescription rates in developed countries. Moreover, Kuriyama et al. have indicated that there are no differences in the clinical outcomes of patients using penicillin V, amoxicillin or a combination of amoxicillin and clavulanate [22].

The second most commonly used antibiotic was amoxicillin, which is considered one of safest empirical antibiotics. It has an appropriate spectrum of activity for oral bacteria and can reach an effective gingival concentration at the site of action [23].

Co-amoxiclav (53.5%) and amoxicillin (35.9%) were the most frequently used antibiotics, with a combined prescription rate of 89.4%, whereas the combined prescription rate for the other 4 antibiotics was only 10.6% of all prescriptions.

Ceftriaxone (J01DD04) was the third most frequently used antibiotic, with a 0.11 DID (5.4% of the total prescribed antibiotics). Because ceftriaxone is a parenteral, third-generation cephalosporin, its use in primary dental care is not considered rational and is not supported by clinical evidence. This antibiotic is prescribed for the treatment of dental abscess, and its use in primary dental care could trigger bacterial resistance [24].

Cephalexin was the fourth most commonly used antibiotic, with a 0.09 DID (4.1%), and it is the antibiotic of choice for some dental infections due to its good bone penetration [20].

The use of gentamicin (with a 0.01 DID and 0.5% prescription rate) is considered less rational due to clinical evidence indicating that it should be reserved for the treatment of select Gram-negative infections, usually occurring in hospital settings [17, 25].

During our survey, 10 classes of diagnosis were identified among the total patients according to the International Classification of Diseases (ICD-10). The most common classes of diagnosis were K08 (other diseases of teeth and supportive structures) at 41.2%, K04 (other diseases of hard tissue of teeth) at 37.6% and K02 (dental caries) at 10.8%. The most frequent classes of diagnosis for patients taking antibiotics were very similar to those for all registered patients. For the group of patients who received antibiotics, the predominant class of diagnosis was K08 (other diseases of teeth and supportive structures) at 62.5%, followed by K04 (diseases of pulp and periodical tissues) at 28.5%. A limitation of the present study is that the data was manually collected from patient medical records.

In general, based on our main findings, we recommend improving the system used for data recording, management and maintenance, which may result in a better and more efficient drug prescription monitoring system in primary dental care.

Conclusions

Our results have revealed a high prescription rate of antibiotics in primary dental care in Kosovo. The prescription of parenteral antibiotics such as ceftriaxone and gentamicin is not rational and is absolutely non-compliant with protocols for antibiotic use in primary dental care. The use of broad-spectrum antibiotics should be replaced with that of more narrow-spectrum antibiotics, and a more restrictive prescription pattern should be established; therefore, there is an urgent need for the implementation of national guidelines and an antibiotic policy, especially to establish an antibiotic stewardship program for dental care.
